<b>Experiment No.3</b>
Create a database using Data Definition Language(DDL) and apply integrity constraints for the specified system
Date of Performance:
Date of Submission:

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

---

**Aim:-** Write a query to create tables for each relation in the relational schema of experiment no.2. Apply drop and alter commands on those tables.

**Objective:-** To learn commands of Data Definition Language(DDL) to create and define databases, and also learn to apply integrity constraints for the specified system.

### Theory:

DDL Commands & Syntax:-

Data Definition Language (DDL) is a subset of SQL and a part of DBMS(Database Management System). DDL consist of Commands to commands like CREATE, ALTER, TRUNCATE and DROP. These commands are used to create or modify the tables in SQL.

DDL Commands:

1. Create
2. Alter
3. truncate
4. drop
5. Rename

### CREATE:

This command is used to create a new table in SQL. The user must give information like table name, column names, and their data types.

Syntax-

```
CREATE TABLE table name(  
column 1 datatype,  
column_2 datatype,  
column_3 datatype,  
....  
);
```

### ALTER:

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

---

This command is used to add, delete or change columns in the existing table. The user needs to know the existing table name and can add, delete, or modify tasks easily.

Syntax-

ALTER TABLE table\_name

ADD column name datatype;

TRUNCATE :

This command is used to remove all rows from the table, but the structure of the table still exists.

Syntax\_\_

TRUNCATE TABLE table\_name;

DROP :

This command is used to remove an existing table along with its structure from the Database.

Syntax-

DROP TABLE table name;

RENAME :

It is possible to change name of table with or without data in it using simple RENAME command. We can rename any table object at any point of time.

Syntax-

RENAME TABLE <Table\_Name> To <New\_Table\_Name>;

Implementation:

Table:

The image displays two screenshots of the SQL Developer interface. The top screenshot shows the 'dbms\_practical3' workspace with a 'student' table being created. The bottom screenshot shows the same workspace with a query executed to view the table's contents.

**Top Screenshot: Creating the 'student' table**

**Navigator:**

- SCHEMAS
  - studentdb
    - Tables
      - student
    - Views
    - Stored Procedures
    - Functions
  - studentdb\_schema
  - sys

**SQL Editor:**

```
1 • create table student(  
2     student_name varchar(20),  
3     student_id int(2),  
4     Address varchar(100),  
5     Contact_no int(10),  
6     DOB varchar(10)  
7 );  
8 • select * from student;
```

**Bottom Screenshot: Querying the 'student' table**

**Navigator:**

- SCHEMAS
  - studentdb
    - Tables
      - student
    - Views
    - Stored Procedures
    - Functions
  - studentdb\_schema
  - sys

**SQL Editor:**

```
1 • SELECT * FROM studentdb.student;
```

**Result Grid:**

student_name	student_id	Address	Contact_no	DOB
--------------	------------	---------	------------	-----

# Vidyavardhini's College of Engineering and Technology

Navigator: dbms\_practical3 student student SQL File 3\* x

**SCHEMAS**

Filter objects

- studentdb
  - Tables
    - faculty
    - student
  - Views
  - Stored Procedures
  - Functions
- studentdb\_schema
- sys

```
1 • use studentdb;
2
3 • create table faculty(
4     Faculty_name varchar(50),
5     Faculty_id INT PRIMARY KEY,
6     Phone_no int(11),
7     Salary varchar(10)
8 )
9
10
```

Navigator: dbms\_practical3 student student SQL File 3\* faculty x

**SCHEMAS**

Filter objects

- studentdb
  - Tables
    - faculty
    - student
  - Views
  - Stored Procedures
  - Functions
- studentdb\_schema
- sys

```
1 • SELECT * FROM studentdb.faculty;
```

Result Grid | Filter Rows: | Edit: | Export

	Faculty_name	Faculty_id	Phone_no	Salary
*	NULL	NULL	NULL	NULL

Alter:

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

dbms\_practical3 student student SQL File 3\* SQL File 4\* x faculty

Limit to 1000 rows

```
1 • use studentdb;
2 • alter table faculty
3   add column email varchar(50);
```

Result Grid

Filter Rows:

Edit:

Export/Import:

	Faculty_name	Faculty_id	Phone_no	Salary	email
•	NULL	NULL	NULL	NULL	NULL

Rename:

### Conclusion:

Constraints in Data Definition Language (DDL) are rules applied to the data in a database table to enforce data integrity. They ensure that the data stored in the database meets certain criteria or conditions. Constraints can enforce uniqueness, referential integrity, and data validity. By defining constraints, such as primary key, unique, foreign key, and check constraints, developers can maintain the accuracy, consistency, and reliability of the data stored in the database. Constraints prevent the insertion, deletion, or modification of data that would violate the specified rules, thereby ensuring data integrity.

Data types in Data Definition Language (DDL) define the type of data that can be stored in each column of a database table. They specify the format and range of values that can be assigned to a column, ensuring data integrity and efficient storage.

The significance of data types in DDL lies in:

1. **Data Integrity:** Data types enforce constraints on the values that can be stored in a column, preventing invalid or inappropriate data from being inserted.
2. **Storage Efficiency:** Different data types require different amounts of storage space. By choosing appropriate data types, database designers can optimize storage efficiency and performance.
3. **Data Validation:** Data types help validate the format and range of values entered into a column, ensuring consistency and accuracy of the data.

Commonly used data types in DDL include:

1. **INTEGER/INT:** Used for whole numbers without decimal points, such as 1, 10, -5.

## Vidyavardhini's College of Engineering and Technology

### Department of Artificial Intelligence & Data Science

---

2. VARCHAR(n): Variable-length character strings with a maximum length of 'n'. For example, VARCHAR(50) can store strings of up to 50 characters.
3. CHAR(n): Fixed-length character strings with a length of 'n'. Unused space is padded with spaces. For example, CHAR(10) can store strings of exactly 10 characters.
4. DECIMAL(p, s): Fixed-point numeric data type, where 'p' specifies the total number of digits and 's' specifies the number of digits after the decimal point. For example, DECIMAL(10, 2) can store numbers with up to 10 digits, 2 of which are after the decimal point.
5. DATE: Used to store date values in YYYY-MM-DD format.
6. BOOLEAN: Represents true or false values.

These are just a few examples of commonly used data types in DDL. The choice of data type depends on the nature of the data being stored and the requirements of the application.
